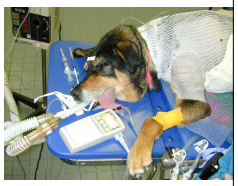
Drug Receptor Interactions

What would you do?

- thoracotomy
- premed: buprenorphine (partial agonist)
- intra-op: fentanyl (full agonist)
- recovery: naloxone (antagonist)
- post op analgesia?



agonist

- A drug which interacts with a specific receptor to produce a response
  - ie, it has efficacy

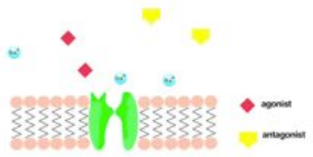
efficacy

- The ability to produce a response after binding

antagonist

- A drug which occupies a receptor stopping an agonist getting in
- it produces no effect on its own
  - ie, it has no efficacy

competitive antagonist



inverse agonist

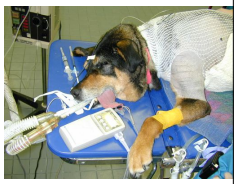
- A drug which occupies a receptor to produce the opposite effect to an agonist
  - ie, it has negative efficacy
- it is also blocked by an antagonist
- constitutive activation required

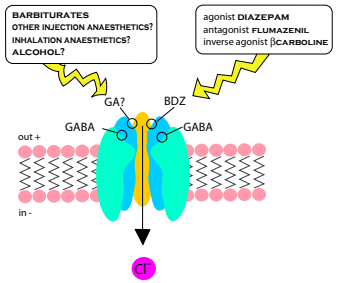
partial agonist

- a drug which occupies a receptor and produces a resonse which is smaller than that of a full agonist
  - ie it has low efficacy

What would you do?

- thoracotomy
- premed: buprenorphine (partial agonist)
- intra-op: fentanyl (full agonist)
- recovery: naloxone (antagonist)
- post op analgesia?





affinity

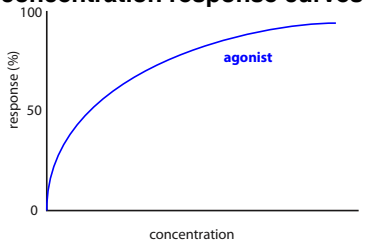
- The tendency of a drug to bind to receptors

$$KA = \frac{1}{KD}$$

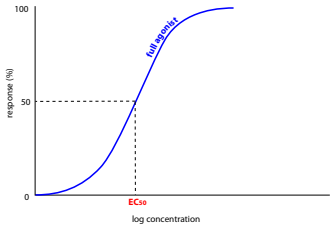
affinity

- high affinity drug
  - high occupancy at low concentration
- low affinity drug
  - high occupancy at high concentration

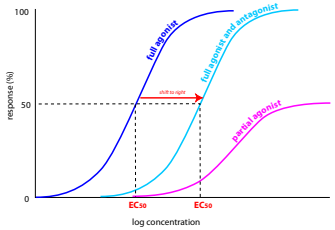
concentration response curves



log concentration response curve



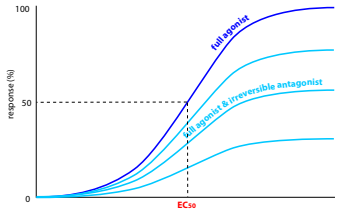
log concentration response curve



antagonism

- competitive
  - reversible
  - irreversible
- non-competitive
  - usually channel blockers
- physiological
- chemical
- pharmacokinetic

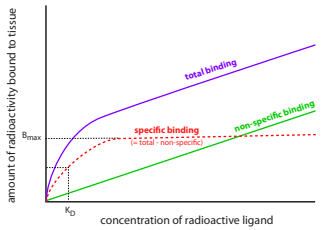
irreversible antagonist



binding assays

- tissues homogenised
- cell membranes collected
- incubated with radioligand
- recovered by filtration & washed
- radioactivity measured
- KD and Bmax calculated

binding assays



autoradiography

receptor activation assays

receptor numbers

- change with use
- up and down regulation

receptor reserve

- = spare receptors
- more receptors in tissue than required for full response
- partial agonists may produce a full response in a tissue with many spare receptors
- common in smooth muscle

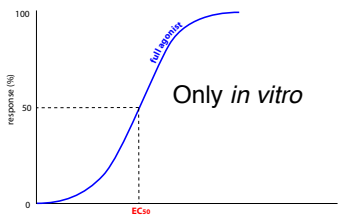
desensitisation / tachyphylaxis (receptors)

- receptor down regulation
- conformation changes
- transducer changes
- mediator depletion

tolerance (animals)

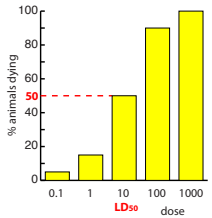
- increased metabolism
- adaptation
  - progession of disease
- drugs pumped out

EC_{50}



Only *in vitro*

ED_{50}



therapeutic ratio

- an index of a drug's safety

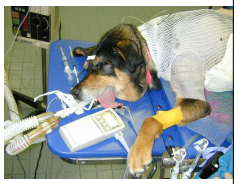
$$= \frac{LD_{50}}{ED_{50}}$$

therapeutic ratio

- difference between effective dose and dose which produces side effects is clinically important
- LD50 ethically unacceptable

What would you do?

- thoracotomy
- premed: buprenorphine (partial agonist)
- intra-op: fentanyl (full agonist)
- recovery: naloxone (antagonist)
- post op analgesia?



drug receptor interactions

- agonists produce an effect
- competitive antagonists block the effect but the blockade can be overcome by increasing the agonist concentration
- drugs can be compared using EC_{50} values in vitro and ED_{50} values in vivo
- therapeutic index is a measure of how safe a drug is
